Exercise sheet 1: Hidden Markov models

Exercise 1 - Two kinds of dice

A casino uses two kinds of dice: 98% of dice are fair and 2% are loaded. The loaded die has a probability of 0.5 to show number six and 0.1 for the numbers one to five.

1a)

When we pick up a die from a table at random, what is the probability of rolling a six?

Hide

Hint 1: Formulae

L = Loaded F = Fair $\mathcal{O} = \text{Observation} P(\mathcal{O}) = P(F) \times P(\mathcal{O}|F) + P(L) \times P(\mathcal{O}|L)$

Hint 2: Calculation Method

$$P(6) = 0.98 \times \frac{1}{6} + 0.02 \times \frac{1}{2}$$

Solution

$$P(6) = 0.173\overline{3}$$

1b)

Hide We pick up a die from a table at random and roll [6 6 6]. What is the probability, that the die is loaded.

Hint 1: Formulae

$$P(L|\mathcal{O}) = \frac{P(L,\mathcal{O})}{P(\mathcal{O})} P(L,\mathcal{O}) = P(\mathcal{O}|L) \times P(L)$$

Hint 2: Calculation Method

$$\begin{split} P(L|\mathcal{O}) &= \frac{P(\mathcal{O}|L) \times P(L)}{P(\mathcal{O}|L) \times P(L) + P(\mathcal{O}|F) \times P(F)} \\ &= \frac{(\frac{1}{2})^3 \times 0.02}{(\frac{1}{2})^3 \times 0.02 + (\frac{1}{6})^3 \times 0.98} \end{split}$$

Solution

$$P(L|\mathcal{O}) = 35.53\%$$

1c)

How many sixes in a row would we need to roll to be at least 90% sure that the die is loaded?

Hide

Hint 1: Formulae

$$P(L|\mathcal{O}) = \frac{P(\mathcal{O}|L) \times P(L)}{P(\mathcal{O}|L) \times P(L) + P(\mathcal{O}|F) \times P(F)}$$

Hint 2: Calculation Method

$$P(L|\mathcal{O}) = \frac{\frac{2}{100} \times (\frac{1}{2})^n}{\frac{2}{100} \times (\frac{1}{2})^n + \frac{98}{100} \times (\frac{1}{6})^n} \ge 0.9 \qquad |\text{split } (\frac{1}{6})^n$$
(1)

$$\frac{\frac{2}{100} \times (\frac{1}{2})^n + \frac{1}{100} \times (\frac{1}{6})^n}{\frac{2}{100} \times (\frac{1}{2})^n + \frac{9}{100} \times (\frac{1}{2})^n \times (\frac{1}{3})^n} \ge \frac{9}{10} \qquad | \text{factorize} \qquad (2)$$

$$\iff \frac{\frac{2}{100} \times (\frac{1}{2})^n + \frac{98}{100} \times (\frac{1}{2})^n \times (\frac{1}{3})^n}{\frac{2}{100} \times (\frac{1}{2})^n \times (1 + 49 \times (\frac{1}{3})^n)} \ge \frac{9}{10} \qquad | \text{simplify, given } n > 0 \qquad (3)$$

$$\iff \frac{1}{1 + 40} \times (\frac{1}{3})^n \qquad \ge \frac{9}{10} \qquad | \text{cross-multiply, given } n > 0 \qquad (4)$$

$$\iff \frac{\frac{2}{100} \times (\frac{1}{2})^n}{\frac{2}{100} \times (\frac{1}{6})^n \times (1 + 49 \times (\frac{1}{6})^n)} \ge \frac{9}{10} \qquad | \text{ simplify, given } n > 0$$
 (3)

$$\iff \frac{1}{1 + 49 \times (\frac{1}{3})^n} \qquad \qquad \ge \frac{9}{10} \qquad | \text{cross-multiply, given } n > 0$$
 (4)

$$\iff \frac{9}{10}(1+49\times(\frac{1}{3})^n) \le 1$$
 | rewrite (5)

$$\iff (\frac{1}{3})^n \qquad \leq \frac{1}{441} \qquad |\ln()$$

$$\iff \left(\frac{1}{3}\right)^n \qquad \leq \frac{1}{441} \qquad |\ln() \qquad (6)$$

$$\iff n \times \ln\left(\frac{1}{3}\right) \qquad \leq \ln\left(\frac{1}{441}\right) \qquad |\times \frac{1}{\ln\left(\frac{1}{3}\right)} \qquad (7)$$

$$\iff n \qquad \qquad \geq \frac{\ln(\frac{1}{441})}{\ln(\frac{1}{2})} \tag{8}$$

$$\iff n$$
 $\geq 5.542487...$ (9)

Solution

n=6, as only Integers make sense here (just trying would also work)

Exercise 2 - The occasionally cheating casino

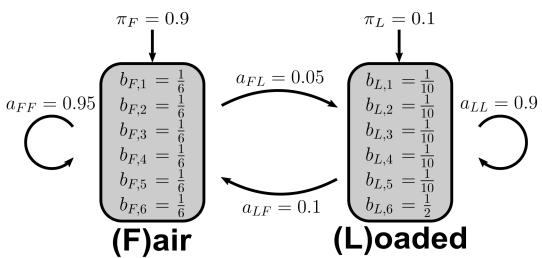

In a casino they use a fair die most of the time, but occasionally they switch to a loaded die. The loaded die has a probability 0.5 to show number six and probability 0.1 for the numbers one to five. Assume that the casino switches from a fair to a loaded die with probability 0.05 before each roll, and that the probability of switching back is 0.1. The probability to start a game with the fair die is 0.9.

2a)

Draw a graphical representation of the described Hidden Markov model.

Hide

Solution

2b)

Given an observed sequence of outcomes $\mathcal{O}=3661634$ and two possible state sequences $s_1=LLLFFFF$ and $s_2=FFFFFFF$ (where F= Fair and L= Loaded), what are the joint probabilities $P(\mathcal{O},s_1)$ and $P(\mathcal{O},s_2)$ in the HMM described above?

Hide

Hint 1: Formulae

$$P(\mathcal{O}, s_x) = P(\mathcal{O}|s_x) \times P(s_x)$$

Hint 2: Calculation Method

$$\begin{split} P(s_1) = & \pi_L \times a_{LL}^2 \times a_{LF} \times a_{FF}^3 = 0.1 \times 0.9^2 \times 0.1 \times (0.95)^3 = 0.0069 \\ P(s_2) = & \pi_F \times a_{FF}^6 = 0.9 \times 0.95^6 = 0.6616 \\ P(\mathcal{O}|s_1) = & b_{L,3} \times b_{L,6}^2 \times b_{F,1} \times b_{F,6} \times b_{F,3} \times b_{F,4} = 0.1 \times 0.5^2 \times (\frac{1}{6})^4 = 1.9 \times 10^{-5} \\ P(\mathcal{O}|s_2) = & b_{F,3} \times b_{F,6}^2 \times b_{F,1} \times b_{F,6} \times b_{F,3} \times b_{F,4} = (\frac{1}{6})^7 = 3.57 \times 10^{-6} \\ P(\mathcal{O},s_1) = & P(\mathcal{O}|s_1) \times P(s_1) = 1.9 \times 10^{-5} \times 0.0069 \\ P(\mathcal{O},s_2) = & P(\mathcal{O}|s_2) \times P(s_2) = 3.57 \times 10^{-6} \times 0.6616 \end{split}$$

Solution

$$P(\mathcal{O}, s_1) = 1.34 \times 10^{-7}$$

 $P(\mathcal{O}, s_2) = 2.36 \times 10^{-6}$

2c)

Give an observation $\mathcal{O} = 1662$, how many possible state sequences exist in the described HMM?

Hide

Hint 1 The actual observation does not matter in this case because all emission probabilities are > 0. There are 2^4 possible state sequences.

Solution There are 16 possible state sequences.

Exercise 3 - Programming assignment

For the programming tasks, please follow the instructions given in GitHub Classroom under the following links.
